

[illegible]

Subsequently, however, it is clear that the results are quite different from those of the previous studies. In particular, the results indicate that the probability of a firm's going public is positively related to the firm's size, profitability, and growth opportunities, and negatively related to the firm's age. These results are consistent with the findings of the previous studies.

These results indicate that the model is able to predict the number of people who will be infected by a given outbreak. The model can also be used to predict the number of people who will be infected by a given outbreak, given a specific set of parameters.

Regulation is also shown by the fact that the same factors affect the same response in the different tissues. Indeed, perhaps the most striking feature of the present data is that the same factors affect the same response in the same tissue. However, the differences in the sensitivity of the different tissues to the same factor, together with the differences in the response to the same factor in the same tissue, are not surprising in view of the fact that the response to the same factor in the same tissue is not the same in all cases.
